

IR1 INTERSECTS HIGH-GRADE LITHIUM & CAESIUM AT TIN MOUNTAIN, SOUTH DAKOTA, USA

HIGHLIGHTS

Phase I drilling at the Tin Mountain Project confirmed significant high-grade lithium and caesium intersections, including:

TDD-24-008

- 5.2m @ 2.05% Li_2O from 39.2m, including:
 - 1.5m @ 3.04% Li_2O from 40.8m

TDD-24-007

- 1.0m @ 1.54% Cs_2O from 31.2m
- Drilling results demonstrate that the pegmatite extends down-dip under cover, remains open at depth, and confirms the lateral extent of mineralisation near-surface
- Phase II drilling will target deeper and central core pegmatite zones with horizontal drilling technology, alongside mineralogical mapping studies to progress towards a maiden mineral resource estimate

IRIS Metals Limited (ASX: IR1) (“IRIS” or “the Company”) is pleased to announce the results of its Phase I diamond drilling program at the **Tin Mountain Project, South Dakota, USA**. The findings confirm high-grade mineralisation and the multi-element potential of the pegmatite.

IRIS Metals President of U.S. Operations, Matt Hartmann, commented:

“The Phase I drill results at Tin Mountain confirms high-grade mineralisation and the multi-element potential of the host pegmatite, including lithium and now caesium. Plans for Phase II are underway to target the central pegmatite zone which proved difficult to access with a conventional surface drilling approach. IRIS will leverage extensive surface exposure and historic mining operations, combined with 2025 advanced technologies, to deepen our understanding of the Tin Mountain Project and advance towards a maiden mineral resource”.

Diamond Drilling Program Summary

A total of 23 diamond drill holes, for a total of 1,122m, were successfully completed during the Phase I program in late 2024. Results have now been received for all holes, including:

TDD-24-006

- 3.0m @ 1.24% Li_2O from 26.0m,
- 3.0m @ 3.20% Li_2O from 36.7m,
- 2.0m @ 1.68% Li_2O from 43.2m

TDD-24-007

- 1.0m @ 1.54% Cs_2O from 31.2m

TDD-24-008

- 5.2m @ 2.05% Li_2O from 39.2m, including:
- 1.5m @ 3.04% Li_2O from 40.8m

TDD-24-017

- 1.2m @ 1.56% Li_2O from 13.7m,
- 1.8m @ 3.90% Li_2O from 23.5m,
- 2.7m @ 1.47% Li_2O from 35.6m, including:
 - 1.0m @ 3.37% Li_2O from 37.3m

TDD-24-021

- 6.7m @ 1.11% Li_2O from 8.3m, including:
 - 2.1m @ 2.29% Li_2O from 12.9m

The drill program utilised HQ and PQ diamond core drilling from the surface, with core logging and sampling conducted at IRIS's core facility in Custer, South Dakota. Laboratory assays were completed by SGS.

Reported drill hole intercepts confirm high-grade lithium within the pegmatite, typical of megacrystic pegmatites. Table 1 summarises all Phase I drill intercepts, and Table 2 presents the location and geometry of all drill holes completed during Phase I program at the Tin Mountain Project.

Lithium mineralisation at Tin Mountain consists of primary magmatic spodumene crystals dispersed within the inner core of a zoned LCT pegmatite. Phase I targets focused on confirming the near-surface lateral extent of the pegmatite and exploring its down-dip extension. However, steep terrain and hazards from historical underground workings limited drill collar placement, adding complexity to the program.

Phase I drilling results confirmed the near-surface lateral extent of the pegmatite and demonstrated that the pegmatite extended down-dip under cover, remaining open at depth. The area beneath the

historical cavern and underground workings was not adequately tested using conventional surface core drilling methods, and now represents the priority exploration target for Phase II.

Figures 1 and 2 illustrate the drill program geometry, with Figure 3 highlighting a high-grade intercept of **5.2m @ 2.05% Li₂O from 39.2m in TDD-24-008**. Significant mineralised zones from **TDD-24-001** and **TDD-24-006** further indicate continuity of mineralisation from surface to the deepest drilled points.

Beyond lithium assays, all core material was analysed for other critical minerals known to exist within the pegmatites of the region.

Historical operations at Tin Mountain identified caesium-bearing pollucite, and Phase I drilling confirmed the presence of recoverable caesium with a notable interval of **1.0m @ 1.54% Cs₂O in TDD-24-007 from 31.2m**. No additional caesium intercepts of significant grade were encountered during the Phase I drilling. IRIS will conduct further studies to identify the caesium-bearing minerals and evaluate recovery methods, aiming to optimise the potential value of additional critical minerals across its Black Hills project portfolio.

Figure 2: Section A-A'

Discussion

Results from the 2024 diamond drilling program confirm that the Tin Mountain Project's pegmatite hosts both high grade lithium and caesium, displays a shallow weathering profile, and remains open at depth with the core yet to be drilled.

Findings from the Phase I drill program have accelerated planning for Phase II, which will deploy a horizontal drill rig positioned on favorable topography to advance lateral core holes beneath the existing cavern and underground workings, targeting the core of the zoned pegmatite.

Additionally, IRIS is planning detailed mineralogical mapping of the outcropping pegmatite to compare mineral distributions between surface exposures and drill core. This will aid in assessing the megacrystic pegmatite and modeling work as IRIS advances Tin Mountain to a maiden mineral resource estimate.

These initial results underscore the project's strategic advantages, including its location in a mining-friendly jurisdiction with robust infrastructure—nearby road, rail, and power—in one of the world's most significant lithium markets. With lithium designated as a critical mineral by the U.S. government, large-scale grants aim to bolster domestic supply chains, reducing reliance on foreign sources and enhancing the economic potential of the Tin Mountain Project.

Ongoing Activities

The Company is preparing for the 2025 field season with drill programs planned across the Beecher, Tin Mountain, and Edison Projects. An expanded airborne geophysics program is underway, building on the smaller survey completed in 2024. This larger effort will target areas within the extensive Federal lands exploration package, aiming to define and permit drill-ready targets for 2025.

Additionally, the Company continues to evaluate and conduct due diligence on potential acquisitions in South Dakota-based tenure to further strengthen its portfolio.

Figure 3: Meter scale spodumene megacrystic 'logs' in the walls of the Tin Mountain Mine.

Tin Mountain Background

The Tin Mountain Project is located 10km from the township of Custer in the Black Hills of South Dakota. The Project is located on private land with a current option agreement held by Iris Metals covering 5.8 hectares. The Tin Mountain Project includes the formerly producing Tin Mountain mine.

The Tin Mountain mine claim was filed in 1889 for tin exploration, and then operated in the late 1920's, and again in 1940's - 1950's. The pegmatite contains a number of critical and industrial minerals including spodumene, amblygonite, beryl, pollucite, muscovite, cassiterite, columbite-tantalite, microlite, quartz and lepidolite. The spodumene crystals contained in the pegmatite are classified as megacrystic "logs" and are some of the largest found in the world. The spodumene megacrysts are up to 14m in length and 1m in width.

The spodumene bearing zone of the Tin Mountain pegmatite has an outcropping strike length of nearly 150m. Historic mining operations have excavated a large cavern at the surface and a small extent of underground workings which lie beneath and adjacent to the cavern.

About The South Dakota Project

The Black Hills of South Dakota are famous for historic lithium mining dating back to 1898 when Li-bearing spodumene and amblygonite was first mined near the township of Custer. IRIS controls 2,105 federal mineral claims and has agreements over two patented claim blocks.

Existing project areas include:

- Beecher Project – including Longview and Black Diamond
- Tin Mountain Project
- Edison Project
- Helen Beryl Project
- Tinton Project

The Beecher pegmatite trend was mined sporadically between the 1920's and 1950's for lithium, beryllium, tantalum, mica and feldspar. Limited amounts of lithium spodumene ore from the Beecher mines was shipped to Hill City during the 1940's where it was processed through a flotation circuit.

IRIS' is currently moving the Beecher Project to near-term development and has been granted mining licenses permitting lithium pegmatite mining for these patented claims.

These mining licenses, granted by the State of South Dakota, enable IRIS to fast-track all exploration and mining activities including the right to explore and mine lithium bearing pegmatites.

Location of IRIS' projects within South Dakota

About IRIS Metals (ASX:IR1)

IRIS Metals Ltd (ASX:IR1) is an exploration company with an extensive suite of assets considered to be highly prospective for hard rock lithium located in South Dakota, United States (US). The company's large and expanding South Dakota Project is located in a mining friendly jurisdiction and provides the company with strong exposure to the battery metals space, and the incentives offered by the US government for locally sourced critical minerals.

The Black Hills have a long and proud history of mining dating back to the late 1800s. The Black Hills pegmatites are famous for having the largest recorded lithium spodumene crystals ever mined. Extensive fields of fertile LCT-pegmatites outcrop throughout the Black Hills with significant volumes of lithium spodumene mined in numerous locations.

Forward looking Statements:

This announcement may contain certain forward-looking statements that have been based on current expectations about future acts, events and circumstances. These forward-looking statements are, however, subject to risks, uncertainties and assumptions that could cause those acts, events and circumstances to differ materially from the expectations described in such forward-looking statements. These factors include, among other things, commercial and other risks associated with exploration, estimation of resources, the meeting of objectives and other investment considerations, as well as other matters not yet known to IRIS or not currently considered material by the company. IRIS accepts no responsibility to update any person regarding any error or omission or change in the information in this presentation or any other information made available to a person or any obligation to furnish the person with further information.

Not an offer in the United States:

This announcement has been prepared for publication in Australia and may not be released to US wire services or distributed in the United States. This announcement does not constitute an offer to sell, or a solicitation of an offer to buy, securities in the United States or any other jurisdiction. Any securities described in this announcement have not been, and will not be, registered under the US Securities Act of 1933 and may not be offered or sold in the United States except in transactions exempt from, or not subject to, the registration requirements of the US Securities Act and applicable US state securities laws.

Competent Persons Statement:

The information in this announcement that relates to exploration results is based on information reviewed by Matt Hartmann, IRIS' President of U.S. Operations, and a Competent Person who is a Member of the Australasian Institute of Mining and Metallurgy (MAusIMM) (318271), a Registered Member of the Society for Mining, Metallurgy and Exploration (RM-SME) (4170350RM). Matt Hartmann is an exploration geologist with over 20 years' experience in mineral exploration, including lithium exploration and resource definition in the western United States, and has sufficient experience in the styles of mineralisation and type of deposit under consideration and to the activity undertaken to qualify as a Competent Person as defined in the 2012 Edition of the Australian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves. Matt Hartmann has consented to the inclusion in this Public Report of the matters based on his information in the form and context in which it appears.

**JORC Code, 2012 Edition – Table 1****Section 1 Sampling Techniques and Data**

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
<i>Sampling techniques</i>	<i>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i>	Core sampling protocols meet industry standard practices. Core sampling is guided by lithology as determined during geological logging (i.e., by a geologist). All pegmatite intervals are sampled in their entirety (half-core), regardless if spodumene mineralization is noted or not (in order to ensure an unbiased sampling approach) in addition to ~1 to 3 m of sampling into the adjacent host rock (dependent on pegmatite interval length) to “bookend” the sampled pegmatite. The minimum individual sample length is typically 0.3-0.5m and the maximum sample length is typically 2.0 m. Targeted individual pegmatite sample lengths are 1.0 m. All drill core is oriented to maximum foliation prior to logging and sampling and is cut with a core saw into half-core pieces, with one half-core collected for assay, and the other half-core remaining in the box for reference.
	<i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i>	All drill holes are routinely logged by Senior geologists with extensive experience in LCT pegmatites and sampling methodology. Equipment such as S.G. scales are designed as such with factory calibration certificates.
	<i>Aspects of the determination of mineralisation that are Material to the Public Report.</i>	Lithium bearing minerals including spodumene weather to clays in the oxidised regolith and are not recognised when drilling encounters pegmatites at shallow depths.

<i>Drilling techniques</i>	<i>Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i>	Diamond drilling was carried out by Scion cutting a mix of PQ and HQ sized core
<i>Drill sample recovery</i>	<i>Method of recording and assessing core and chip sample recoveries and results assessed.</i>	Core recovery is very good and typically exceeds 90%
	<i>Measures taken to maximise sample recovery and ensure representative nature of the samples.</i>	Sample recovery is maximised by using experienced drillers, routine geologists' presence the rig when the tube is pulled, feedback if recovery low/ core missing, Triple tube drilling methods ensure maximum recovery. Penalties for excessive core loss in the contract. Regular cross checking of depth on core blocks to run books and actual core measurements.
	<i>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</i>	Negligible in diamond drill core pegmatite resource drilling
<i>Logging</i>	<i>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.</i>	All drill holes are routinely logged by Senior geologists with extensive experience in LCT pegmatites. Upon receipt at the core shack, all drill core is pieced together, oriented to maximum foliation, metre marked, geotechnically logged (including structure), alteration logged, geologically logged, and sample logged on an individual sample basis. Core box photos are also collected of all core drilled, regardless of perceived mineralization. Specific gravity measurements of pegmatite are also collected at systematic intervals for all pegmatite drill core using the water immersion method, as well as select host rock drill core. The logging is qualitative by nature, and includes estimates of spodumene grain size, inclusions, and model mineral estimates.

		These logging practices meet or exceed current industry standard practices.
	<i>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</i>	The core logging is qualitative by nature, and includes estimates of spodumene grain size, inclusions, and model mineral estimates. Geological logging adheres to the Company policy and includes lithological, mineralogical, alteration, veining and weathering.
	<i>The total length and percentage of the relevant intersections logged.</i>	All holes were logged in full.
<i>Sub-sampling techniques and sample preparation</i>	<i>If core, whether cut or sawn and whether quarter, half or all core taken.</i>	Drill core sampling follows industry best practices. Drill core was saw-cut with half-core sent for geochemical analysis and half-core remaining in the box for reference. The same side of the core was sampled to maintain representativeness. Sample sizes are appropriate for the material being assayed. A Quality Assurance / Quality Control (QAQC) protocol following industry best practices was incorporated into the program and included systematic insertion of quartz blanks and certified reference materials (CRMs) into sample batches at a rate of approximately 5% each. Additionally, analysis of pulp-split and course-split sample duplicates were completed to assess analytical precision at different stages of the laboratory preparation process, and external (secondary) laboratory pulp-split duplicates were prepared at the primary lab for subsequent check analysis and validation at a secondary lab. All protocols employed are considered appropriate for the sample type and nature of mineralization and are considered the optimal approach for maintaining representativeness in sampling.
	<i>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</i>	NA.

	<i>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</i>	Core samples definted and marked to lithological boundaries where logical, saw on site at a purpose built core saw facility, and put in callicoe bags for freight to the Laboratory. Samples in the ore zone are taken at a minimum of 0.3m and maximum of 1m down hole.
	<i>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</i>	Standards and duplicates were inserted every 20 samples - blanks were inserted every 50 samples.
	<i>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</i>	Results of standards, duplicates and blanks will be compared to the expected results for quality control
	<i>Whether sample sizes are appropriate to the grain size of the material being sampled.</i>	The ideal mass of 2kg-3kg samples is appropriate to the sampling methodology and the material being sampled.
<i>Quality of assay data and laboratory tests</i>	<i>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i>	Core samples collected were shipped to SGS for standard sample preparation (code PRP89) which includes drying at 105°C, crush to 75% passing 2 mm, riffle split 250 g, and pulverize 85% passing 75 microns. The samples were homogenized and subsequently analyzed for multi-element (including Li and Ta) using sodium peroxide fusion with ICP-AES/MS finish (codes GE_ICP91A50 and GE_IMS91A50). The assay techniques are considered appropriate for the nature and type of mineralization present, and result in a total digestion and assay for the elements of interest. The Company relies on both its internal QAQC protocols (systematic quarter-core duplicates, blanks, certified reference materials, and external checks), as well as the laboratory's internal QAQC. For assay results disclosed, samples have passed QAQC review.

	<i>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</i>	NA.
	<i>Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established.</i>	Standards and duplicates were inserted every 20 samples - blanks were inserted every 50 samples. Along with standard laboratory check methods.
<i>Verification of sampling and assaying</i>	<i>The verification of significant intersections by either independent or alternative company personnel.</i>	Intervals are reviewed and compiled by the Exploration Manager and Project Managers prior to disclosure, including a review of the Company's internal QAQC sample analytical data.
	<i>The use of twinned holes.</i>	No twinned holes have been completed.
	<i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i>	Data is stored directly into excel templates, including direct import of laboratory analytical certificates as they are received. The Company employs various on-site and post QAQC protocols to ensure data integrity and accuracy.
	<i>Discuss any adjustment to assay data.</i>	Adjustments to data include reporting lithium and tantalum in their oxide forms, as it is reported in elemental form in the assay certificates. Formulas used are $Li_2O = Li \times 2.1527$, and $Cs_2O = Cs \times 1.0602$
<i>Location of data points</i>	<i>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</i>	Sample locations were recorded using a handheld GPS using the NAD83_13 Datum. At the end of the drill programs Collars were picked up external by registered surveyors using differential GPS in NAD83_134 Datum
	<i>Specification of the grid system used.</i>	
	<i>Quality and adequacy of topographic control.</i>	
<i>Data spacing and distribution</i>	<i>Data spacing for reporting of Exploration Results.</i>	Sampling undertaken was of a reconnaissance nature and widespread across the pegmatite bodies.

	<i>Whether the data spacing, and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i>	Holes are generally drilled on a 40m grid. Based on the nature of the mineralization and continuity in geological modelling, it is believed that a 40 m spacing will be sufficient to support a mineral resource estimate.
	<i>Whether sample compositing has been applied.</i>	N/A for Diamond Drilling. The pegmatites were sampled in full (no compositing.)
<i>Orientation of data in relation to geological structure</i>	<i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i>	Drill holes were generally designed orthogonal to the general trend of the pegmatites as mapped at surface. No bias is determined.
	<i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i>	
<i>Sample security</i>	<i>The measures taken to ensure sample security.</i>	Chain of custody is maintained by Iris personnel on site and sent in sealed pallets and bags to the Laboratory.
<i>Audits or reviews</i>	<i>The results of any audits or reviews of sampling techniques and data.</i>	Results were reviewed and deemed reliable for the nature of the testing.
Section 2 Reporting of Exploration Results		

(Criteria listed in the preceding section also apply to this section.)		
Criteria	JORC Code explanation	Commentary
<i>Mineral tenement and land tenure status</i>	<i>Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.</i>	The project is in South Dakota USA, the project comprises free-hold patented claims optioned by Iris Metals
	<i>The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</i>	No known impediments.
<i>Exploration done by other parties</i>	<i>Acknowledgment and appraisal of exploration by other parties.</i>	No modern exploration has been conducted at this Project
<i>Geology</i>	<i>Deposit type, geological setting and style of mineralisation.</i>	LCT-pegmatite hosted lithium spodumene mineralisation similar in nature to other zoned lithium pegmatite deposits mined around the world
<i>Drill hole Information</i>	<i>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:</i>	The relevant table is provided in Tables 1 and 2 of the text.
	<i>easting and northing of the drill hole collar</i>	
	<i>elevation or RL (Reduced Level - elevation above sea level in metres) of the drill hole collar</i>	
	<i>dip and azimuth of the hole</i>	
	<i>down hole length and interception depth</i>	
	<i>hole length.</i>	
	<i>If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.</i>	

<i>Data aggregation methods</i>	<i>In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated.</i>	NA.
	<i>Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low-grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.</i>	No specific grade cap or cut-off was used during grade width calculations. Pegmatites have inconsistent mineralization by nature, resulting in most intervals having a small number of poorly mineralized samples throughout the interval included in the calculation. Non-pegmatite internal dilution is limited to typically <4 m where relevant intervals indicated where assays are reported. Intercepts are calculated using weighted averages to compensate for differing sample lengths.
	<i>The assumptions used for any reporting of metal equivalent values should be clearly stated.</i>	No metal equivalents have been reported.
<i>Relationship between mineralisation widths and intercept lengths</i>	<i>These relationships are particularly important in the reporting of Exploration Results.</i>	Relationship between mineralisation widths and intercept lengths
	<i>If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.</i>	Geological modelling is ongoing; however, current interpretation supports a large pegmatite body (Tin Mountain) of flat dipping 20 degrees towards the north. All reported widths are close to true widths but may vary from hole to hole based on the drill hole angle and the highly variable nature of pegmatite bodies, which tend to pinch and swell aggressively along strike and to depth. i.e. The dip of the mineralized pegmatite body may vary in a dip sense and along strike, so the true widths are not always apparent until several holes have been drilled in any drill-fence. The logistics of placing drill pads was also limiting in this phase, so multiple holes were fanned from one pad
	<i>If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known').</i>	If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. Cross sections with drill holes and interpretation also accompany the results when reported.

<i>Diagrams</i>	<i>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported. These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.</i>	Provided in the text.
<i>Balanced reporting</i>	<i>Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced avoiding misleading reporting of Exploration Results.</i>	Please refer to the table(s) included herein as well as those posted on the Company's website. Results for every individual pegmatite interval that is greater than 1 m @ 1.0%Li₂O has been reported. Drill holes with no significant results are also reported as such.
<i>Other substantive exploration data</i>	<i>Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.</i>	Various mandates required for advancing the Project towards economic studies have been or are about to be initiated, including but not limited to, metallurgy, geomechanics, hydrogeology, hydrology, stakeholder engagement, geochemical characterization, as well as transportation and logistical studies.
<i>Further work</i>	<i>The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling).</i>	Drone geophysical magnetic and radiometric surveys have been flown. Future Drill testing is being planned, further mapping and rock chip, soil sampling, is also ongoing.
	<i>Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.</i>	Will be provided when drill results and further exploration data has been reviewed.
